I am running paris 3.0 with a p4 processor and 2 gigs of ddr ram. My computer suddenly started to lock up when i try to boot paris, and it gives me a message that the program is trying to execute non-executable memory. It advises me to load the the program again, so I deleted and re-installed. I get the same results. I also took out my video card and switched to on board display. Does anyone know what is happening?

Joe, have you installed any new plugins recently?

For my Paris boot, I have to disable the no-execute protection for AutoTune 1.3. But I didn't think this was available in the P4...

"Rohde,

I just removed auto tune 1.3, but I don't think it was removed. It still shows up in programs add and remove. Still having the same problem after a complete removal of paris and all program files.
