If you are clocking an RME HDSP card from a Paris ADAT card (or in my case clocking 3 x RME cards from 3 x Paris ADAT cards) and, for convenience sake, since you want to be able to monitor your HDSP I/O in Wavelab without launching Paris in order to clock the HDSP cards and you are too f***in lazy to make one simple change in a digital patchbay GUI , you decide to also hook one of the RME cards up directly to a WC feed from your external clock that is also feeding your 4 x MECs which are then sending this WC sync from the ADAT modules to the RME interfaces because "since the ADAT modules are just regenerating the WC that they are receiving from the house clock this should be the same" you will have loads of fun when both computers start losing sync, and not only losing sync, but freezing completely, requiring a hard reboot. Not only will it be fun while it's happening, but you get the added benefit of having to actually shut down every computer and digital device in the studio for a little while, then after they have calmed down a little, start your boot sequence all over. The various devices may still be pissed off at each other for a while and you may need to try a couple of times before all of this stuff is willing to shake hands and play nice.

That's about as simple as I can explain it.

;o)

And your point??

:)

I figured a bunch of folks were on the brink of going down this road and it
was my duty to stop them before it was too late.....of course

;o)
